Data Wrangling

with pandas
Cheat Sheet
http://pandas.pydata.org

Syntax – Creating DataFrames

	ŭ	2	5	8	11		
	e	2	6	9	12		
df = pd.DataFrame(
			: [4				
			: [7				
			: [1				
<pre>index = pd.MultiIndex.from_tuples(</pre>							
	[•		•		('e',2)]	
		nai	mes=	['n'	,'v']))	
Create D	ataFr	ame v	vith a	Multi	Index		

Method Chaining

Most pandas methods return a DataFrame so that another pandas method can be applied to the result. This improves readability of code.

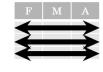

Tidy Data – A foundation for wrangling in pandas

In a tidy data set:

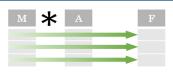

in its own column

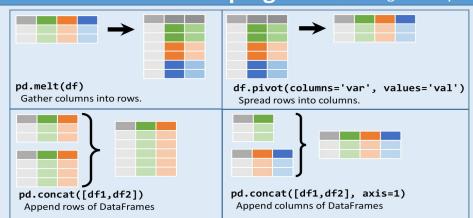

Tidy data complements pandas's vectorized operations. pandas will automatically preserve observations as you manipulate variables. No other format works as intuitively with pandas.

Each **observation** is saved in its own **row**

M * A

Reshaping Data – Change the layout of a data set

df.sort_values('mpg')
Order rows by values of a column (low to high).

df.sort_values('mpg',ascending=False)
Order rows by values of a column (high to low).

df.rename(columns = {'y':'year'})
Rename the columns of a DataFrame

df.sort_index()

Sort the index of a DataFrame

df.reset_index()
 Reset index of DataFrame to row numbers, moving
 index to columns.

df.drop(columns=['Length','Height'])
Drop columns from DataFrame

Subset Observations (Rows)

Logic in Python (and pandas)

df.column.isin(values)

pd.isnull(obj)

pd.notnull(obj)

Greater than or equals &, |, ~, ^, df.any(), df.all()

df[df.Length > 7]
 Extract rows that meet logical

criteria.

df.drop_duplicates()

Remove duplicate rows (only considers columns).

df.head(n)
 Select first n rows.
df.tail(n)

Gf.tall(n)
Select last n rows.

Less than

Equals

Greater than

Less than or equals

df.sample(frac=0.5)

Randomly select fraction of rows.

df.sample(n=10)

Randomly select n rows.

df.iloc[10:20]
Select rows by position.

df.nlargest(n, 'value')
 Select and order top n entries.

df.nsmallest(n, 'value')
Select and order bottom n entries.

Not equal to

Is NaN

Is not NaN

Group membership

Logical and, or, not, xor, any, all

Subset Variables (Columns)

df[['width','length','species']]
Select multiple columns with specific names.

df['width'] or df.width

Select single column with specific name.

df.filter(regex='regex')

Select columns whose name matches regular expression regex.

regex (Regular Expressions) Examples				
'\.'	Matches strings containing a period '.'			
'Length\$'	Matches strings ending with word 'Length'			
'^Sepal'	Matches strings beginning with the word 'Sepal'			
'^x[1-5]\$'	Matches strings beginning with 'x' and ending with 1,2,3,4,5			
'^(?!Species\$).*'	Matches strings except the string 'Species'			

df.loc[:,'x2':'x4']

Select all columns between x2 and x4 (inclusive).

df.iloc[:,[1,2,5]]

Select columns in positions 1, 2 and 5 (first column is 0).

df.loc[df['a'] > 10, ['a','c']]

Select rows meeting logical condition, and only the specific columns .

Summarize Data

df['w'].value counts()

Count number of rows with each unique value of variable

len(df)

of rows in DataFrame.

df['w'].nunique()

of distinct values in a column.

df.describe()

Basic descriptive statistics for each column (or GroupBy)

pandas provides a large set of summary functions that operate on different kinds of pandas objects (DataFrame columns, Series, GroupBy, Expanding and Rolling (see below)) and produce single values for each of the groups. When applied to a DataFrame, the result is returned as a pandas Series for each column. Examples:

sum()

Sum values of each object.

count()

Count non-NA/null values of each object.

median()

Median value of each object. quantile([0.25,0.75])

Quantiles of each object.

apply(function)

df.expanding()

df.rolling(n)

applied cumulatively.

applied to windows of length n.

Apply function to each object.

min()

Minimum value in each object.

Maximum value in each object.

mean() Mean value of each object.

var()

Variance of each object.

std()

Standard deviation of each object.

Group Data

df.groupby(by="col")

Return a GroupBy object, grouped by values in column named "col".

df.groupby(level="ind")

Return a GroupBy object, grouped by values in index level named "ind".

All of the summary functions listed above can be applied to a group. Additional GroupBy functions:

size() agg(function)

Size of each group. Aggregate group using function.

Windows

Return an Expanding object allowing summary functions to be

Return a Rolling object allowing summary functions to be

Handling Missing Data

df.dropna()

Drop rows with any column having NA/null data.

df.fillna(value)

Replace all NA/null data with value.

Make New Columns

df.assign(Area=lambda df: df.Length*df.Height)

Compute and append one or more new columns.

df['Volume'] = df.Length*df.Height*df.Depth Add single column.

pd.qcut(df.col, n, labels=False)

Bin column into n buckets.

pandas provides a large set of vector functions that operate on all columns of a DataFrame or a single selected column (a pandas Series). These functions produce vectors of values for each of the columns, or a single Series for the individual Series. Examples:

max(axis=1)

Element-wise max. Element-wise min.

clip(lower=-10,upper=10) abs()

Trim values at input thresholds Absolute value.

The examples below can also be applied to groups. In this case, the function is applied on a per-group basis, and the returned vectors are of the length of the original DataFrame.

shift(1)

Copy with values shifted by 1. rank(method='dense')

Ranks with no gaps.

rank(method='min') Ranks. Ties get min rank.

rank(pct=True)

Ranks rescaled to interval [0, 1].

rank(method='first')

Ranks. Ties go to first value.

shift(-1)

min(axis=1)

Copy with values lagged by 1.

cumsum()

Cumulative sum.

cummax()

Cumulative max.

cummin()

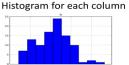

Cumulative min.

cumprod()

Cumulative product.

Plotting

df.plot.hist()

df.plot.scatter(x='w',y='h') Scatter chart using pairs of points
